

ABOUT MORTALITY DATA FOR FRANCE, CIVILIAN POPULATION

by Dana Glej, John Wilmoth, Magali Barbieri, Jacques Vallin, and France Meslé
Last revised by Magali Barbieri

GENERAL

The Human Mortality Database (HMD) includes two data series for France: one for the Total Population (including military) and one for the Civilian Population. This document includes only the information that is specific to the civilian data series. For more general information regarding the demographic data for France, please see the *Background and Documentation* for the Total Population.

With the exception of 1914-1920 and 1940-45, the period data in this series are identical to those given for the total population. Although we include cohort life tables in this civilian series, we caution the user that they are of questionable value for cohorts that experienced significant war losses.

Specific Episodes in French Demographic History

France entered World War I (WWI) on August 3, 1914; the armistice ending WWI was signed on November 11, 1918. France entered World War II on September 3, 1939; although the war in Europe did not end until "V.E. day" (May 8, 1945), French war operations ended in June 1940.

Source of Data

Civilian death counts come from annual vital statistics publications by the *Institut national de la statistique et des études économiques* (INSEE) with corrections for false stillbirths prior to 1975 (Vallin 1973, Vallin and Meslé 2001); for more information regarding "false stillbirths", see the *Background and Documentation* for the Total Population. With the exception of war years, population estimates originally came from INSEE and were republished by Vallin and Meslé (2001). Civilian population estimates for males in 1914-20 and 1941-45, and for females in 1942-45 come from Vallin (1973, pp. 268-271, 282-287).

DEATH COUNT DATA

Coverage and Completeness

The data cover the civilian national population. Only deaths recorded by INSEE are included; deaths reported by the military authority are not included. Civilian death counts (reported by INSEE) differ from total death counts (estimated by Vallin 1973; Vallin and Meslé 2001) only for: 1914-19 & 1940-45 among males; and 1942-45 among females. Vallin (1973, p. 313) notes that for females during 1914-19, there was no difference between "total" and "civilian" mortality. He further notes (p. 345) that differences between total and civilian mortality were minimal for females in 1939-1942 and for males in 1939.

POPULATION COUNT DATA

Coverage and Completeness

During wartime, population estimates (as of January 1st) exclude active military personnel. In fact, during World War II (WWII), the population estimates exclude only military POWs. Because of the short duration of French war operations during WWII (September 1939–June 1940), Vallin (1973) argues that subtracting the effective military forces from the January 1st population would risk overestimating civilian mortality because the majority of military personnel were not exposed to risk of military mortality. Consequently, Vallin estimates the population *présente* (for 1939-45) rather than the true civilian population; nonetheless, we use the term “civilian population” to refer to these estimates.

Specific Details

The civilian population (estimated by Vallin, 1973) differs from the total population estimates only for: 1914-20 & 1941-45 among males; and 1942-45 among females. For 1920, the differences between the January 1st population for civilian versus total males were quite small (14,480,300 vs. 14,925,000, respectively; Vallin, 1973, p. 268-273).

For details regarding how civilian population estimates were derived, see Chapter V in Vallin (1973) and Section 3 in Gleit et al. (2005).

DATA QUALITY ISSUES

- There is a notable increase in death rates among males aged 18-50 during 1914-19 and 1941-45, but in most cases these civilian rates are substantially lower than the death rates for the total population of males during wartime.
- Nonetheless, among males aged 20-21 in 1919, civilian death rates are higher than the total population (e.g., $M_{21}=0.076$ for civilian males vs. $M_{21}=0.015$ for all males—see Figure 1). The main source of this difference appears to be especially low civilian population estimates. For example, among males in 1919, the number of total deaths was 3,254 versus 2,585 for civilian males, but the estimate of the total population on 1/1/1919 was 230,200 versus 30,100 for civilian males. Thus, the death rate is higher because the denominator (exposure) is smaller.
- A similar problem occurs in 1941 among males aged 22-47: civilian death rates are higher even than total death rates (e.g., $M_{23}=0.0087$ for civilian males and $M_{23}=0.0063$ for all males). Again, it appears that civilian population estimates for these groups are especially low, resulting in higher death rates.

Figure 1. Death rates by sex and age, Civilian versus Total Population, France, 1919
